COMPUTER SCIENCE MENTORS 61A

April 3 to April 7, 2017

1 What Would Scheme Print?

- 1. What will Scheme output? Draw box-and-pointer diagrams to help determine this.
 - (a) (cons (cons 1 nil) (cons 2 (cons (cons 3 (cons 4 5)) (cons 6 nil))))
 - (b) (define a 4) ((lambda (x y) (+ a)) 1 2)
 - (c) ((lambda (x y z) (y x)) 2 / 2)
 - (d) ((lambda (x) (x x)) (lambda (y) 4))
 - (e) (define boom1 (/ 1 0))
 - (f) boom1
 - (g) (define boom2 (lambda () (/10)))
 - (h) (boom2)

(i) Why/How are the two "boom" definitions above different?

- (j) How can we rewrite boom2 without using the lambda operator?
- 2. What will Scheme output?

```
(a) (if (/ 1 0) 1 0)
```

(d) (and 1
$$\#f$$
 (/ 1 0))

- (h) (and (and) (or))
- (i) Given the lines above, what can we say about interpreting if expressions and booleans in Scheme?

3. The following line of code does not work. Why? Write the lambda equivalent of the let expressions.

2 Scoping

- 4. What is the difference between dynamic and lexical scoping?
- 5. What would this print using lexical scoping? What would it print using dynamic scoping?

```
a = 2
def foo():
    a = 10
    return lambda x: x + a
bar = foo()
bar(10)
```

6. How would you modify and environment diagram to represent dynamic scoping?

7. Implement waldo. waldo returns #t if the symbol waldo is in a list. You may assume that the list passed in is well-formed.

```
scm> (waldo '(1 4 waldo))
#t
scm> (waldo '())
#f
scm> (waldo '(1 4 9))
#f
```

Extra challenge: Define waldo so that it returns the index of the list where the symbol waldo was found (if waldo is not in the list, return #f).

```
scm> (waldo '(1 4 waldo))
2
scm> (waldo '())
#f
scm> (waldo '(1 4 9))
#f
```
